Background:	The cell cycle in Arabidopsis thaliana mediates organ morphogenesis, cell proliferation and differentiation, and these functions are restricted to the eristems. The cell cycle is controlled by cyclin-dependent kinases, which bind to positive regulators called cyclins. In particular, Arabidopsis B-type cyclin controls cell cycle progression by regulating gene expression late in the G2 and M phases. Expression of cyclin Ds have been shown to increase in response to sucrose. Cdc2 and Cdc2B control cell cycle progression after forming a complex with cyclin.

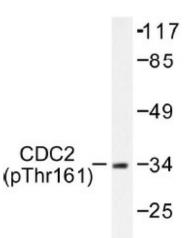

Prolifera and pelota are required for DNA replication and meiotic cell division, respectively.
