Summary: The eukaryotic cell cycle is governed by cyclin-dependent protein kinases (CDKs) whose

activities are regulated by cyclins and CDK inhibitors. The protein encoded by this gene is a member of the cyclin family and contains the cyclin box. The encoded protein lacks the protein destabilizing (PEST) sequence that is present in other family members. Transcriptional

activation of this gene can be induced by tumor protein p53. Two transcript variants

encoding the same protein have been identified for this gene. [provided by RefSeq, Jul 2008]
