Background: Variant histone H2A which replaces conventional H2A in a subset of nucleosomes.

Nucleosomes wrap and compact DNA into chromatin, limiting DNA accessibility to the cellular

machineries which require DNA as a template. Histones thereby play a central role in transcription regulation, DNA repair, DNA replication and chromosomal stability. DNA

accessibility is regulated via a complex set of post-translational modifications of histones, also called histone code, and nucleosome remodeling. Required for checkpoint-mediated arrest of cell cycle progression in response to low doses of ionizing radiation and for efficient repair of

DNA double strand breaks (DSBs) specifically when modified by C-terminal phosphorylation

Synonyms: H2A; H2A.X; H2AX; X
