Background: The protein encoded by this gene is a zinc finger transcription factor that binds to GC-rich motifs of many promoters. The encoded protein is involved in many cellular processes; including cell differentiation; cell growth; apoptosis; immune responses; response to DNA damage; and chromatin remodeling. Post-translational modifications such as phosphorylation; acetylation; glycosylation; and proteolytic processing significantly affect the activity of this protein; which can be an activator or a repressor. Three transcript variants encoding different isoforms have been found for this gene.
