Background:	This gene product belongs to the histone deacetylase family. Histone deacetylases act via the formation of large multiprotein complexes; and are responsible for the deacetylation of lysine residues at the N-terminal regions of core histones (H2A; H2B; H3 and H4). This protein forms transcriptional repressor complexes by associating with many different proteins; including YY1; a mammalian zinc-finger transcription factor. Thus; it plays an important role in transcriptional regulation; cell cycle progression and developmental events. Alternative splicing results in multiple transcript variants.
