Background: This gene encodes a deubiquitinating enzyme that is phosphorylated at the onset of mitosis

and then dephosphorylated at the metaphase/anaphase transition. It can deubiquitinate H2A, one of two major ubiquitinated proteins of chromatin, in vitro and a mutant form of the protein was shown to block cell division. Alternate transcriptional splice variants, encoding

different isoforms, have been characterized.

Synonyms: UBP-M; UBPM

Protein Families: Protease
