Background: This gene encodes a TBP- (TATA box-binding protein) associated phosphoprotein that

represses both basal and activated levels of transcription. The encoded protein is

phosphorylated in vivo and this phosphorylation affects its interaction with TBP. This protein contains a histone fold motif at the amino terminus, a TBP-binding domain, and a glutamine-and alanine-rich region. The binding of DR1 repressor complexes to TBP-promoter complexes

may establish a mechanism in which an altered DNA conformation, together with the

 $formation \ of \ higher \ order \ complexes, \ inhibits \ the \ assembly \ of \ the \ preinitiation \ complex \ and$

controls the rate of RNA polymerase II transcription. [provided by RefSeq, Jul 2008]
