Background: The incorporation of selenocysteine into a protein requires the concerted action of an mRNA

element called a sec insertion sequence (SECIS), a selenocysteine-specific translation

elongation factor and a SECIS binding protein. With these elements in place, a UGA codon can be decoded as selenocysteine. The gene described in this record encodes a nuclear protein that functions as a SECIS binding protein. Mutations in this gene have been associated with a reduction in activity of a specific thyroxine deiodinase, a selenocysteine-containing enzyme,

and abnormal thyroid hormone metabolism.
