**Background:** Transglutaminases are enzymes that catalyze the crosslinking of proteins by epsilon-gamma

glutamyl lysine isopeptide bonds. While the primary structure of transglutaminases is not conserved, they all have the same amino acid sequence at their active sites and their activity is calcium-dependent. The protein encoded by this gene consists of two polypeptide chains activated from a single precursor protein by proteolysis. The encoded protein is involved the

later stages of cell envelope formation in the epidermis and hair follicle.

**Synonyms:** MGC126249; MGC126250; TG(E); TGE; Transglutaminase-3
