Background: Stable cohesion between sister chromatids before anaphase and their timely separation

during anaphase are critical for chromosome inheritance. In vertebrates, sister chromatid

cohesion is released in 2 steps via distinct mechanisms. The first step involves

phosphorylation of STAG1 (MIM 604358) or STAG2 (MIM 300826) in the cohesin complex. The second step involves cleavage of the cohesin subunit SCC1 (RAD21; MIM 606462) by ESPL1, or separase, which initiates the final separation of sister chromatids (Sun et al., 2009 [PubMed

19345191]).[supplied by OMIM, Nov 2010]
