| Background:           | The Fos gene family consists of 4 members: FOS, FOSB, FOSL1, and FOSL2. These genes<br>encode leucine zipper proteins that can dimerize with proteins of the JUN family, thereby<br>forming the transcription factor complex AP-1. As such, the FOS proteins have been<br>implicated as regulators of cell proliferation, differentiation, and transformation. Alternatively<br>spliced transcript variants encoding different isoforms have been found for this gene.<br>[provided by RefSeq, Jul 2008] |
| Synonyms:             | AP-1; G0S3; GOS3; GOSB   |

## **Product images:**

HEK293T cells were transfected with the pCMV6-ENTRY control (Left lane) or pCMV6-ENTRY FOSB ([RC207004], Right lane) cDNA for 48 hrs and lysed. Equivalent amounts of cell lysates (5 ug per lane) were separated by SDS-PAGE and immunoblotted with anti-FOSB. Positive lysates [LY402011] (100ug) and [LC402011] (20ug) can be purchased separately from OriGene.
