Summary:	Mammalian mitochondrial ribosomal proteins are encoded by nuclear genes and help in protein synthesis within the mitochondrion. Mitochondrial ribosomes (mitoribosomes) con of a small 28S subunit and a large 39S subunit. They have an estimated 75% protein to rRN composition compared to prokaryotic ribosomes, where this ratio is reversed. Another difference between mammalian mitoribosomes and prokaryotic ribosomes is that the latter contain a 5S rRNA. Among different species, the proteins comprising the mitoribosome diff greatly in sequence, and sometimes in biochemical properties, which prevents easy recognition by sequence homology. This gene encodes a 28S subunit protein that contains high level of sequence similarity with ribosomal protein S11P family members. A pseudoge corresponding to this gene is found on chromosome 20. Multiple transcript variants encod different isoforms have been found for this gene. [provided by RefSeq, Apr 2016]
