Summary: The protein encoded by this gene belongs to the RGS (regulator of G protein signaling) family.

Members of the RGS family act as GTPase-activating proteins on the alpha subunits of heterotrimeric, signal-transducing G proteins. This protein inhibits signal transduction by increasing the GTPase activity of G protein alpha subunits, thereby driving them into their inactive GDP-bound form. Alternative splicing occurs at this locus and four transcript variants

encoding distinct isoforms have been identified. [provided by RefSeq, Nov 2013]
