Summary: The protein encoded by this gene is a member of the transmembrane 4 superfamily, also known as the tetraspanin family. Most of these members are cell-surface proteins that are characterized by the presence of four hydrophobic domains. The proteins mediate signal transduction events that play a role in the regulation of cell development, activation, growth and motility. This encoded protein is a cell surface glycoprotein that is known to complex with integrins. This protein appears to promote muscle cell fusion and support myotube maintenance. Also it may be involved in signal transduction. This gene is localized in the tumor-suppressor gene region and thus it is a candidate gene for malignancies. Two transcript variants encoding different isoforms have been found for this gene. [provided by RefSeq, Jul 2014]

Plasma neuronal-derived exosome levels of CD81, measured by ELISA using recombinant CD81 (OriGene TP317508) as the standard, were not statistically different among cognitively normal controls (CNC), mild cognitive impairment (MCI), MCI converting to AD (ADC), and Alzheimer's disease patients (AD).
